

Demo Script — Salesforce Login Email Verification

Audience: Stakeholders / Reviewers **Duration:** ~10 minutes **Prerequisites:** Solution deployed, Login Flow assigned to Standard Login and SSO

Setup Before the Demo

- ☐ Clear all existing verification records:

```
delete [SELECT Id FROM Verification_Code__c];
```

- ☐ Have the test user's email inbox open and visible
 - ☐ Log the test user out of Salesforce
 - ☐ Open <https://login.salesforce.com> (or your My Domain URL)
-

Scenario 1 — Happy Path (Correct Code)

Shows: Code is emailed, entered correctly, login succeeds.

Steps:

1. Enter the test user's credentials and click **Log In**
2. The **Verification Code** screen appears (flow running) ← *point this out*
3. Switch to the email inbox — a new email arrives with the subject "**Your Salesforce Verification Code**"
4. Note the 6-digit code in the email
5. Enter the code in the input field on screen
6. Click **Next**
7. User is now inside the org ☒

Talking point: "The code expires in 5 minutes. It is stored as a SHA-256 hash — plain text is never saved in the database."

Scenario 2 — Wrong Code → Error Message → Attempts Counter

Shows: Wrong codes show inline error; attempts are tracked.

Steps:

1. Log the user out again
2. Log back in — verification screen appears; a new code is emailed
3. Type **999999** (wrong code) → click **Next**
4. **Error message appears:** "Invalid code. 2 attempts remaining." ← *point this out*
5. Type **000000** (wrong code again) → click **Next**
6. **Error message:** "Invalid code. 1 attempt remaining."

Talking point: "Errors show inline — no page reload. The user sees exactly how many attempts they have left."

Scenario 3 — Three Wrong Codes → Block & Forced Logout

Shows: After 3 wrong codes, the user is blocked and the session is destroyed.

Steps (continuing from Scenario 2):

1. Type **111111** (wrong code, 3rd attempt) → click **Next**
2. **Blocked screen appears:** "You have entered 3 incorrect verification codes. For your security, you are being logged out. Please log in again after 10 minutes."
3. Click **OK**
4. Browser redirects to <https://login.salesforce.com> — session destroyed ☒

Talking point: "The Finish button triggers `LoginFlow_FinishLocation = /secur/Logout.jsp`. No matter what path the user takes on this screen — they cannot reach the org. The session is destroyed at the platform level, not the browser level."

Scenario 4 — Refresh While Blocked (Session Guard)

Shows: Refreshing the browser during or after a block does not bypass the system.

Steps:

1. Log the user back in within 10 minutes of the block ← *this is the key moment*
2. Instead of completing Scenario 3's block screen, demonstrate: go back to login, log in again
3. The **Force Logout screen** appears immediately: "You have exceeded the maximum number of verification attempts. Click OK to be logged out."
4. No code was emailed — the check happened before code generation ← *point this out*
5. Click **OK** → redirected to login.salesforce.com

Talking point: "`VerificationCodeChecker` runs at the very start of every flow execution — before generating or sending a code. Even if the user opens a new browser tab, they cannot bypass the block."

Scenario 5 — Expired Code

Shows: Codes older than 5 minutes are rejected and a new one is auto-sent.

Steps:

1. Log the user in and let the verification screen sit idle for more than 5 minutes (*or temporarily shorten `CODE_EXPIRY_MINUTES` in `VerificationCodeService` for the demo*)
2. Enter any code from the old email
3. Flow detects the expired code and **automatically sends a new email**
4. The screen refreshes, prompting the user to check their inbox for a new code

Talking point: "Codes are valid for exactly 5 minutes. Attempting to use an old code after expiry triggers a fresh send — no action required from the user beyond entering the new code."

Scenario 6 — SSO (Google SAML) Path

Shows: The flow applies to SSO users, not just standard logins.

Steps:

- 1. Navigate to the My Domain URL (or SSO entry point)
- 2. Click **Log In with Google**
- 3. Complete Google authentication
- 4. The **Verification Code** screen appears ← *same UI as standard login*
- 5. Enter the code from email → access granted ☒

Talking point: *"The Login Flow is assigned at both the Login Page level and the SSO configuration level. All users — regardless of identity provider — must pass email verification."*

Scenario 7 — Block Expires (10-Minute Window)

Shows: The block is temporary — after 10 minutes the user can log in normally.

Steps:

- 1. Attempt to log in while blocked → force logout screen appears
- 2. Wait 10 minutes (or show the timestamp on the blocked `Verification_Code__c` record)
- 3. Log in again → verification screen appears normally
- 4. Enter the correct code → access granted ☒

Talking point: *"There is no permanent ban. The block window is 10 minutes — a configurable constant in one Apex class. An admin can also manually unblock a user immediately via a simple anonymous Apex query."*

Summary Talking Points

Feature	Detail
Works for all users	SSO + standard login
Code validity	5 minutes
Max attempts	3
Block duration	10 minutes
Code storage	SHA-256 hash only
Session handling	Server-side logout via <code>LoginFlow_FinishLocation</code>
Test coverage	19/19 tests passing
Deployment method	ZIP via Workbench (Metadata API v62.0)
